BLINKIT SALES & BUSINESS PERFORMANCE ANALYTICS

A practical business intelligence and operations review

PROJECT SUMMARY

I built this dashboard to bring several parts of Blinkit's business into one view and explore what the supplied data could tell me about sales, delivery operations, customer feedback, marketing activity, and inventory. I also documented data limitations rather than treating every number as automatically reliable.

EXECUTIVE DASHBOARD VIEW

11.01M	**5,000**	**69.40%**
Reported sales*	Reported orders*	On-time deliveries
3.34 / 5	**1.97×**	**12.86%**
Average rating*	Overall marketing ROAS	Dairy & Breakfast share

*Previously reported dashboard KPIs; source CSVs were not available for independent recalculation in this report revision. Overall ROAS was recalculated from the supplied marketing CSV.

01 | Executive Summary

This project brings several business views into one Power BI report. The dashboard makes core indicators easy to scan, while the supporting analysis looks more closely at delivery status, product sales, marketing performance, and inventory records.

The supplied data shows a few useful patterns: about seven in ten delivery records were marked on time; Dairy & Breakfast had the highest category-level item sales; and recalculated campaign ROAS ranged from approximately 1.94× to 2.03×. Inventory records also contained inconsistencies that should be investigated before the figures are used as operational measures.

At a glance

Area	What the data says	Why it matters
Delivery	30.60% of records were not marked On Time.	Compare delays by status, time, distance, and recorded reasons.
Products	Dairy & Breakfast contributed 12.86% of item-level sales.	Category performance can guide further product-level review.
Marketing	Campaign ROAS ranged from 1.94× to 2.03×.	Compare ROAS with campaign cost, audience, and objectives.
Inventory	Some damaged-stock values exceed stock received.	Validate definitions and records before interpreting the ratio.

Project objectives

- Bring sales and operational indicators into a single-page dashboard.
- Compare product, delivery, customer, and marketing performance.
- Identify patterns that deserve further investigation.
- Document data-quality issues and avoid unsupported conclusions.

The report describes a prepared project dataset and is not an official report of current Blinkit operations.

02 | Project Scope & Data Architecture

I organised the analysis around practical business questions: How are sales trending? Which products and categories contribute most? How often are deliveries late? How do campaigns compare on revenue relative to spend? What should be checked before trusting the inventory figures?

Datasets used

Dataset	Records	Main fields used
Delivery	5,000	Delivery status, delivery time, distance, delay reason
Marketing	5,400	Campaign, spend, revenue, impressions, clicks, conversions
Items	5,000	Product ID, quantity, unit price, item sales
Products	268	Product name, category, brand, price, product ID
Inventory	75,172	Product ID, date, stock received, damaged stock

How I approached the analysis

- Reviewed available columns, row counts, and key totals.
- Grouped delivery records by status and calculated each status share.
- Matched item records to product details using product_id, then aggregated sales by category and product.
- Recalculated campaign ROAS as total revenue divided by total spend.
- Compared inventory totals and counted rows where damaged stock exceeded stock received.

The Power BI dashboard uses DAX measures for KPI cards and Power Query for data preparation. The supporting checks are described separately; the report does not imply that all source tables could be joined into one unified model.

Important distinction: order-level sales and item-level sales come from different tables. The orders dataset available during the dashboard build did not include an order_id field, so the two sales figures are not directly reconcilable using the supplied files.

03 | Delivery Performance & Fulfillment

The delivery dataset contains 5,000 records. I grouped them by delivery status to understand how often deliveries were marked on time or delayed.

Delivery status	Records	Share
On Time	3,470	69.40%
Slightly Delayed	1,037	20.74%
Significantly Delayed	493	9.86%
Not on time (combined)	1,530	30.60%

What I took from the results

Around three in ten delivery records were not marked On Time. That makes delivery performance a useful area for further investigation, especially when comparing delivery status against distance, delivery time, and recorded delay reasons.

The dashboard also includes a distance-versus-delivery-time scatter plot. The points are spread across the available distance range, but this pattern alone does not establish what caused delays. Road congestion, order preparation, dispatch timing, and other factors would need to be tested with suitable data before making causal claims.

Suggested next check

- Compare average and distribution of delivery times across status groups.
- Review available delay reasons and check for missing values.
- Avoid treating distance as the sole explanation for delivery delays.

The delivery analysis identifies patterns in the supplied dataset; it does not establish a measured reduction in delays or prove the cause of any delay.

04 | Product Category & Item Sales

The item dataset contains 5,000 rows and totals 4,972,415.43 in item-level sales. I matched the item records to product details using product_id and then compared sales by category and individual product.

Finding	Item-level sales	Share of item sales
Dairy & Breakfast category	639,222.19	12.86%
Vitamins product	260,822.01	5.25%

Category performance

Dairy & Breakfast was the highest-selling category in the supplied item and product data, contributing 12.86% of total item-level sales. Pharmacy and Fruits & Vegetables were also among the stronger categories in the category chart. These results describe sales value, not profit or margin.

Individual product performance

Vitamins was the highest-selling individual product by item-level sales, with 260,822.01, or approximately 5.25% of the item-level total. Other products appearing among the top sales results included Pet Treats, Cough Syrup, Toilet Cleaner, and Bread.

How I would use this finding

- Review top-performing categories alongside margin and stock availability.
- Compare product sales with inventory activity before recommending changes to stock allocation.
- Treat sales contribution as one input to assortment decisions, rather than a standalone measure of business value.

The item-level sales total is separate from the reported order-level sales KPI. The two figures should not be compared as if they represent the same transaction measure.

05 | Marketing, Customer Sentiment & Payments

Marketing performance

I recalculated campaign ROAS using total revenue generated divided by total spend, rather than relying only on the pre-calculated ROAS field. Across the supplied marketing records, total spend was 16,319,838.24 and total revenue generated was 32,193,407.37, giving an overall recalculated ROAS of approximately 1.97×.

Campaign	Spend	Revenue	ROAS
Referral Program	—	—	2.03× (highest)
New User Discount	1,833,455	3,603,860	1.97×
Membership Drive	1,790,070	3,524,951	1.97×
Festival Offer	1,796,687	3,507,064	1.95×
Flash Sale	1,831,688	3,556,087	1.94×
Category Promotion	1,850,583	3,582,455	1.94× (lowest)

ROAS is a revenue-to-spend comparison, not a profit measure. Other costs and campaign objectives may not be represented, so a lower ROAS should prompt further review rather than an automatic decision to stop a campaign.

Customer sentiment and payment methods

Previously reported dashboard results showed positive sentiment at 34.76%, negative sentiment at 32.84%, and neutral sentiment at 32.40%. Payment methods were also distributed relatively evenly: Cash on Delivery 25.70%, UPI 25.14%, Wallet 24.88%, and Card 24.28%. The original feedback and orders CSVs were not available for independent recalculation in this report revision, so these are retained as previously reported dashboard values.

The similarity between negative sentiment and delivery delay percentages may justify further investigation, but it does not prove that delivery timing caused negative feedback. Linking feedback to individual delivery records would be needed to test that relationship.

06 | Data Quality & Audit Findings

Checking data quality was an important part of this project. Some figures could be analysed directly, while other records need clarification before the results can be used for operational decisions.

Inventory check	Result
Inventory rows	75,172
Total stock received	147,526 units
Total damaged stock recorded	80,268 units
Damaged stock ÷ received stock	54.41% aggregate ratio
Rows where damaged stock > stock received	29,255
Rows with positive damaged stock and zero received	28,411

Inventory interpretation

The aggregate ratio of 54.41% should not be presented as a confirmed damage rate. The business meaning, time period, and recording rules for stock received and damaged stock need to be verified. In particular, many rows show damaged stock exceeding received stock, including records with zero stock received.

Sales figures do not reconcile

Measure	Reported total
Order-level sales reported during dashboard build	11,009,308.50
Item-level sales from uploaded items file	4,972,415.43
Difference	6,036,893.07

The orders file lacks order_id, so the difference cannot be fully explained from the available files alone. I report these measures separately rather than treating one as validation of the other.

Other limitations

- The original orders, customers, and feedback CSVs were not available for independent recalculation in this report revision.
- The supplied data is a prepared project dataset, not a live feed of current Blinkit operations.
- Observed associations should not be described as proof of causation.
- Campaign profitability cannot be concluded from ROAS alone.

07 | Recommendations & Conclusion

What I would investigate next

1. Understand delivery delays.

Compare delivery time and distance across status groups, then review recorded delay reasons to identify patterns that deserve operational attention.

2. Review product performance.

Use category and product-level sales to identify high-contributing items, then compare sales with margin and stock data before recommending assortment changes.

3. Look beyond ROAS.

Compare campaign results alongside spend, conversions, audience, and campaign objectives. Use lower-ROAS campaigns as a starting point for review, not an automatic reason to stop them.

4. Validate inventory definitions.

Confirm whether stock received and damaged stock refer to the same products and periods, and investigate records where damaged stock exceeds received stock.

5. Reconcile sales data.

Add or recover a reliable order key and document the definitions behind order-level and item-level sales before comparing them directly.

Conclusion

Building this dashboard helped me practise turning multiple datasets into a business-focused Power BI report. I used KPI cards and visualisations to make key patterns easier to review, and treated data validation as part of the analysis rather than an afterthought. The main outcome is not just a set of numbers: it is a clearer view of what the available data suggests, what it does not yet prove, and which questions I would explore next.

Project focus: business performance analysis through interactive visualisation, KPI development, and transparent data-quality reporting.

Prepared as a data analytics portfolio project. This report describes the supplied datasets and analysis performed for the project; it is not an official Blinkit business report.
